Content

1. Stream ciphers and block ciphers
2. Block Cipher Principles
3. Data Stream ciphers and block ciphers
4. Confusion & Diffusion
5. Data Encryption Standard (DES)
6. Avalanche Effect
7. Strength of DES
8. Design principles of block cipher

INDEX

Stream cipher and Block Cipher:

A stream cipher is one that encrypts a digital data stream one bit or one byte at a time.
Examples:
 Autokeyed Vigenère cipher
 A5/1
 RC4
 Vern
 am
 ciph
 er.

Stream cipher and Block Cipher:

Stream cipher and Block Cipher:

A block cipher is one in which a block of plaintext is treated as a whole and used to produce a ciphertext block of equal length. Typically, a block size of 64 or 128 bits is used.
**Examples:**
Feistel cipher
DES
Triple DES
AES

Stream cipher and Block Cipher:

Block Cipher Principle – Fiestel Structure

Plaintext (2w bits)

L_0 w bits w bits R_0

Round 1 K_1

$\oplus$ F

L_1 R_1

Round n K_n

$\oplus$ F

L_n R_n

L_{n+1} R_{n+1}

Ciphertext (2w bits)

1. Plaintext is split into 32-bit halves L_i and R_i
2. R_i is fed into the function F.
3. The output of function F is then XORed with L_i
4. Left and right half are swapped.

$$R_i = L_{i-1} \oplus F(R_{i-1}, K_i)$$

$$L_i = R_{i-1}$$

7

Block Cipher Principle – Fiestel Structure

1. **Block size:** Common block size of 64-bit. However, the new algorithms uses a 128-bit, 256-bit block size.
2. **Key size:** Key sizes of 64 bits or less are now widely considered to be
   insufficient, and 128 bits has become a common size.
3. **Number of rounds**: A typical size is 16 rounds.
4. **Round function F:** This phase consisting of sixteen rounds of the same function, which involves both permutation and substitution functions. Again, greater complexity generally means greater resistance to cryptanalysis.
5. **Subkey generation algorithm:** For each of the sixteen rounds, a different subkey (Ki) derived from main key by the combination of a left circular shift and a permutation. Greater complexity in this algorithm should lead to greater difficulty of cryptanalysis.
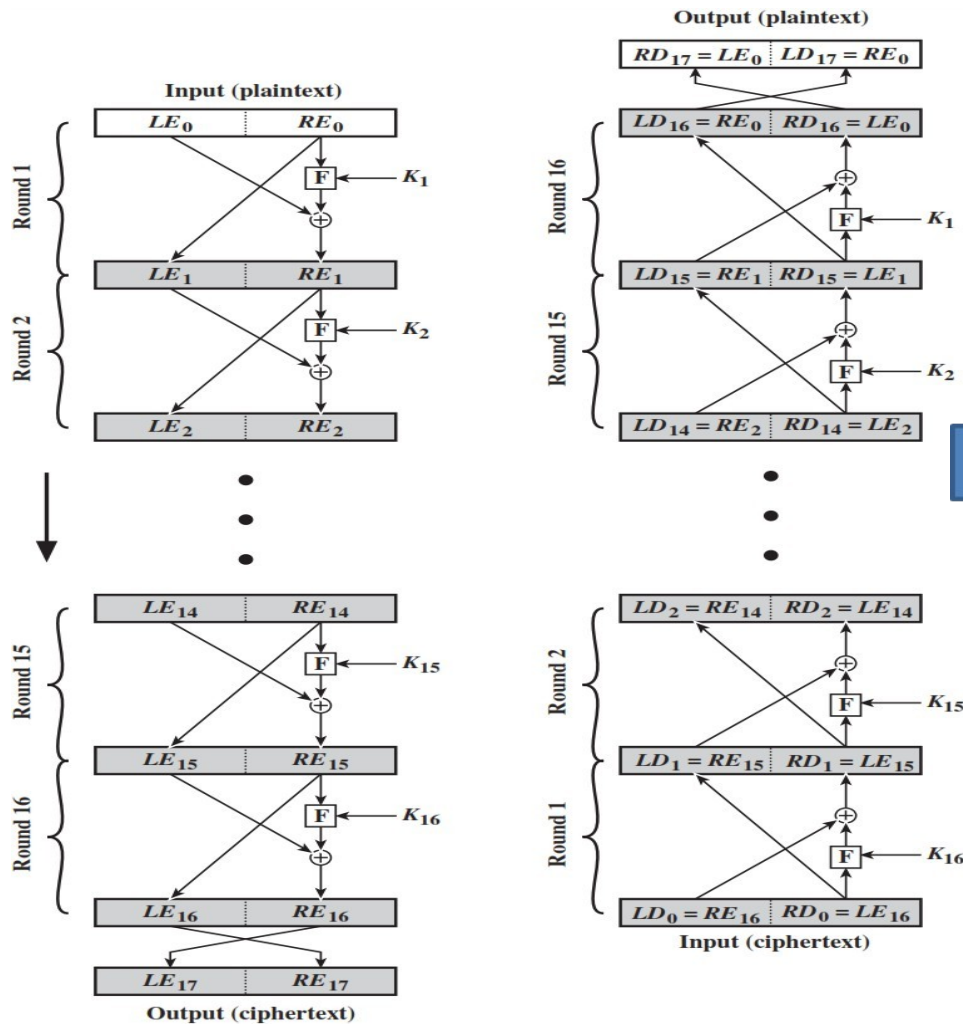

Block Cipher Principle – Fiestel Structure
Prove that o/p of first round of Decryption is equal to 32-bit swap o i/p of 16th round of Encryption LD1=RE15 & RD1=LE15

On Encryption Side:

$$LE_{16} = RE_{15}$$

$$RE_{16} = LE_{15} \oplus F(RE_{15}, K_{16})$$

9

Block Cipher Principle – Fiestel Structure

On Decryption Side:

$$LD_1 = RD_0 = LE_{16} = RE_{15}$$

$$RD_1 = LD_0 \oplus F(RD_0, K_{16})$$

$$= RE_{16} \oplus F(RE_{15}, K_{16})$$

$$= [LE_{15} \oplus F(RE_{15}, K_{16})] \oplus F(RE_{15}, K_{16})$$

$$Thus,$$
$$LD_1 = RE_{15} \ \& \ RD_1 = LE_{15}$$

XOR Associativity Property
$$\because [A \oplus B] \oplus C = A \oplus [B \oplus C]$$

Stream cipher and Block Cipher:

A block cipher is one in which a block of plaintext is treated as a whole and used to produce a ciphertext block of equal length. Typically, a block size of 64 or 128 bits is used.
**Examples:**
Feistel cipher
DES
Triple DES
AES

Stream cipher and Block Cipher:

Confusion & Diffusion:

| **Confusion**	**Diffusion**
• Confusion hides the relationship between the cipher text and the key.	• Diffusion hides the relationship between the cipher text and the plaintext.
• This is achieved by the use of a complex substitution algorithm.	• This is achieved by changing one plaintext digit which affect the value of many cipher text digits.

X1=0010 1011   Diffusion   Y1=1011 1001

X2=0000 1011   Y2=0110 1100

Data Encryption Standard (DES):

1. Initial permutation: First, the 64-bit plaintext passes through an initial permutation (IP) that rearranges the bits to produce the permuted input.
2. The F function: This phase consisting of sixteen rounds of the same function, which involves both permutation and substitution functions.
3. Swap: L and R swapped again at the end of the cipher, i.e., after round 16 followed by a final permutation.
4. Inverse (Final) permutation: It is the inverse of the initial permutation.
5. Subkey generation: For each of the sixteen rounds, a different subkey (Ki) derived from main key by the combination of a left circular shift and a permutation.

Data Encryption Standard (DES): - Initial Permutation

The initial permutation of the DES algorithm changes the order of the plaintext prior to the first round of encryption
16 Rounds

The final permutation occurs after the sixteen rounds of DES are completed. It is the inverse of the initial permutation.

# Data Encryption Standard (DES): The f Function – The Expansion Function

Main purpose: **Increases diffusion**

Since Ri-1 is a 32-bit input and Ki is a 48-bit key, we first need to expand Ri-1 to 48 bits.

Input: (8 blocks, each of them consisting 4 bits) - 32 bits

**Output**: (8 blocks, each of them consisting 6 bits) – 48 bits

R_{i-1}

32

Expansion/permutation
(E table)

24	25	26	27	28	29
28	29	30	31	32	1

# Data Encryption Standard (DES): XOR round Key

XOR Round Key

After the expansion permutation, DES uses the XOR operation on the expanded right section and the round key.

Note that both the right section and the key are 48-bits in length now.

R_{i-1}

32

Expansion/permutation
(E table)

48

K_i

XOR

48

48
Data Encryption Standard (DES): S-Box substitution

- Eight substitution tables.
- 6 bits of input
- 4 bits of output.
- Convert 48 bits to 32 bits
- Non-linear and resistant to differential cryptanalysis.
- Crucial element for DES security!
- Introduces confusion.

Data Encryption Standard (DES): S-Box substitution

The outer two bits of each group select one row of an S-box.
Inner four bits selects one column of an S-box.

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
0	14	04	13	01	02	15	11	08	03	10	06	12	05	09	00	07

Input | 0 | 1 | 1 | 0 | 0 | 1 | Output | 1 | 0 | 0 | 1 |
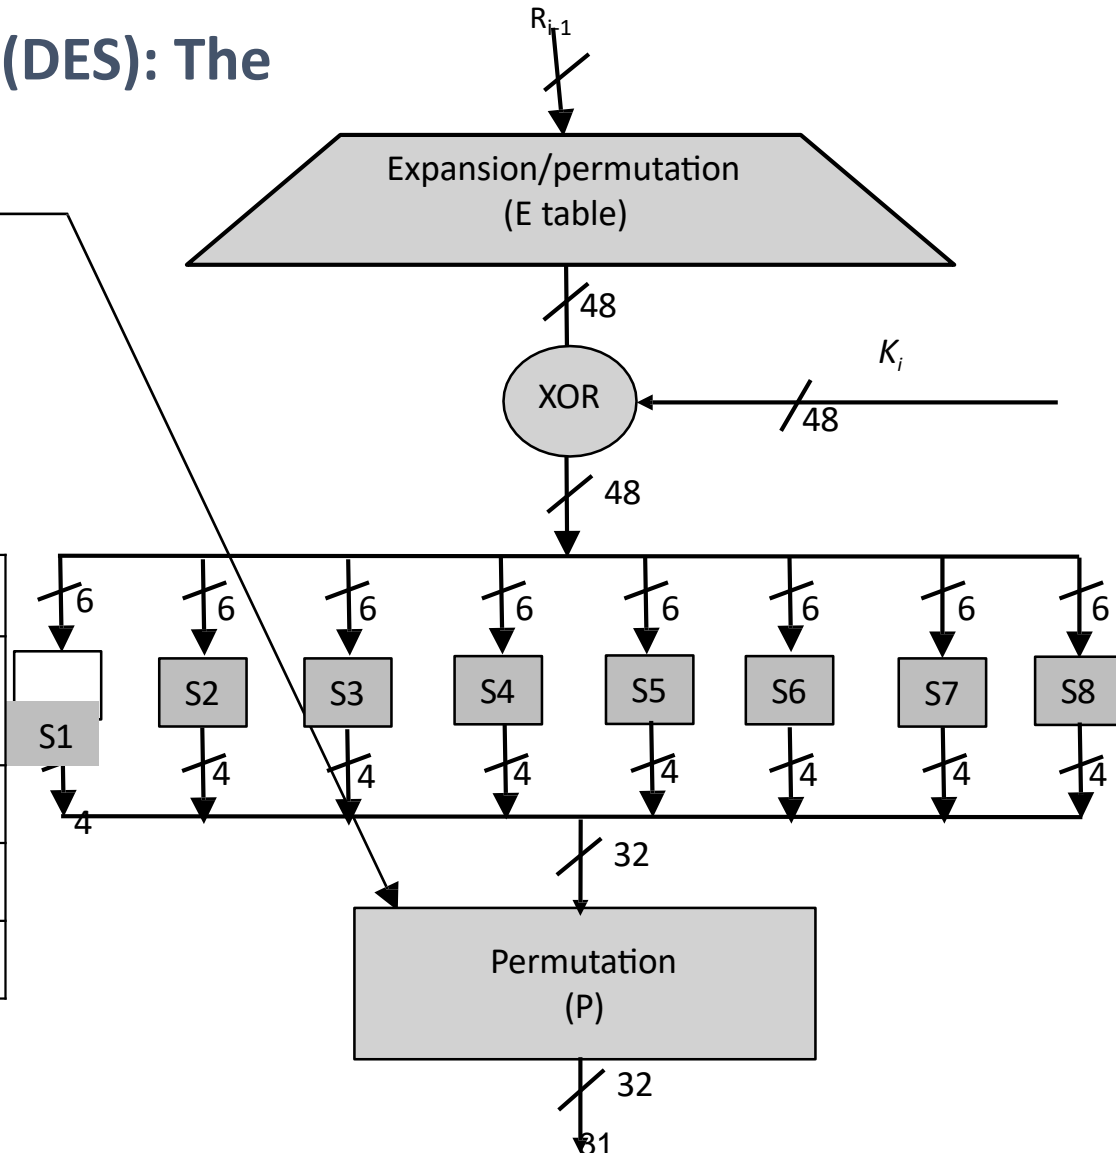

Row   Column

Data Encryption Standard (DES): The Permutation 3_2

Permutation P

- Bitwise permutation.
- **Introduces diffusion.**

Permutation Table P							
16	7	20	21	29	12	28	17
01	15	23	26	05	18	31	10
02	08	24	14	32	27	03	09
19	13	30	06	22	11	04	25

Avalanche Effect

Desirable property of any encryption algorithm is that a change in one bit of the plaintext or of the key should produce a change in many bits of cipher text.
DES performs strong avalanche effect.

Plaintext: 0000000000000000   Key: 22234512987ABB23
Ciphertext: 4789FD476E82A5F1

Plaintext: 000000000000000**1**   Key: 22234512987ABB23
Ciphertext: 0A4ED5C15A63FEA3

Although the two plaintext blocks differ only in the rightmost bit, the cipher text blocks differ in 29 bits.
This means that changing approximately 1.5 % of the plaintext creates a change of approximately 45 % in the ciphertext.

Strength of DES

The use of 56-bit keys: 56-bit key is used in encryption, there are 256 possible keys. A brute force attack on such number of keys is impractical.

The nature of algorithm: Cryptanalyst can perform cryptanalysis by exploiting the characteristic of DES algorithm but no one has succeeded in finding out the weakness.

Design Principle of Block Cipher :

1. ConfusionPurpose: Make the relationship between the ciphertex and the encryption key as complex as possible.Achieved by: Using substitution operations (like S-boxes).
   Effect: Even a small change in the key or plaintext causes major,
   unpredictable changes in ciphertext.

2. DiffusionPurpose: Spread the influence of a single plaintext bit across many ciphertext bits. Achieved by: Using permutation and mixing operations.
   Effect: Changing one bit of the plaintext affects many bits of the ciphertext.

Design Principle of Block Cipher :

3.Kerckhoffs's Principle : A cipher should remain secure even if everything about the system (except the key) is public knowledge. Focuses security entirely on the secrecy of the key, not the algorithm.

4.Iterative Structure (Rounds)Instead of a single operation, block ciphers apply multiple rounds of transformations. Each round improves confusion and diffusion.
Example: AES uses 10, 12, or 14 rounds depending on key size.

5.Key Expansion The key schedule algorithm generates a different subkey for each round from the original key. Strong key expansion ensures better security.
